ABG-VBG Analysis

Brian Locke, Anila Mehta

Table of contents

1 Data Pre-processing

This code pulls in the master database (a STATA file) and does some initial cleaning - this will only need to be run once, and then the data can be accessed in the usual way.

```
# put this in your first R chunk
if (!requireNamespace("kableExtra", quietly = TRUE)) install.packages("kableExtra")
library(kableExtra)
library(gtsummary)

# globally tighten gtsummary/gt tables (smaller font + tighter padding)
gtsummary::theme_gtsummary_compact()
```

```
Setting theme "Compact"
```

```r
# helper: turn any gtsummary table into a PDF-safe, auto-scaling LaTeX table
to_pdf_table <- function(tbl, font_size = 8, landscape = FALSE,
                         label_col_width = NULL) {
  kbl <- gtsummary::as_kable(
    tbl,
    format    = "latex",
    booktabs  = TRUE,
    longtable = TRUE # allows multipage tables; repeats header with kableExtra option below
  )

  # optional: set a fixed width for the first (label) column to encourage wrapping
  if (!is.null(label_col_width)) {
    kbl <- kableExtra::column_spec(kbl, 1, width = label_col_width)
  }

  kbl <- kableExtra::kable_styling(
    kbl,

Converts the data from a STATA format to rdata if the rdata file does not exist. If it does already exist, it just loads that.

```r
# data_dir_name <- '/Users/blocke/Box Sync/Residency Personal Files/Scholarly Work/Locke Research Projects/abg-vbg-project/dat
data_dir_name <- '/Users/reblocke/Research/abg-vbg-project/data'

rdata_file <- file.path(data_dir_name, "full_trinetx.rdata")
stata_file <- file.path(data_dir_name, "full_db.dta")

if (!dir.exists(data_dir_name)) {
  dir.create(data_dir_name)
  message("Directory 'data' created.")
} else {
  message("Directory 'data' already exists.")
}
```

```
Directory 'data' already exists.
```

```r
if (file.exists(rdata_file)) {
  load(rdata_file)
  message("Loaded existing dataset from 'full_trinetx.rdata'.")
} else {
  message("RData file not found. Reading Stata dataset...")
  stata_data <- read_dta(stata_file)

  message("Extracting variable labels...")
  var_label(stata_data)

  message("Extracting value labels...")
  sapply(stata_data, function(x) if (is.labelled(x)) val_labels(x))

  save(stata_data, file = rdata_file)
  message("Dataset saved as 'full_trinetx.rdata'.")

  load(rdata_file)
  message("Loaded newly saved dataset from 'full_trinetx.rdata'.")
```

```
}
```

```
Loaded existing dataset from 'full_trinetx.rdata'.
```

Creating subset_data

```
set.seed(123)
rows_to_keep <- round(nrow(stata_data) * 1)
subset_data <- stata_data[sample(nrow(stata_data), rows_to_keep), ]

subset_data <- subset_data %>%
  filter(encounter_type != 1)

table(subset_data$encounter_type)
```

```
     2      3
171727 343559
```

```
dim(subset_data)
```

```
[1] 515286    546
```

Generating Codebook for the Full Dataset

```
message("Generating codebook for the dataset...")
```

```
Generating codebook for the dataset...
```

```r
study_codebook <- codebookr::codebook(
  stata_data,
  title = "Full TrinetX",
  subtitle = "Dataset Documentation",
  description = "This dataset contains patient-level records from the TrinetX database.
                 It has been processed and converted from the original Stata file."
)
codebook_file <- file.path(data_dir_name, "codebookr.docx")
print(study_codebook, codebook_file)
message("Codebook saved as 'codebookr.docx' in the data directory.")
```

```
Codebook saved as 'codebookr.docx' in the data directory.
```

New Variable - Death at 60 days

Odds ratios are computed within each blood-gas cohort.
Reference = patients in the normal PCO2 range.
Below normal: <35 mmHg. Above normal: >45 mmHg (ABG, Calc-ABG) or >50 mmHg (VBG).
Because the underlying cohorts differ (ABG, VBG, Calculated ABG), denominators are not identical across groups.

Inverse Propensity Weighting

IPW done using Gradient Boosting Methods (GBM) - a type of decision-tree based machine learning. "***Random forests and GBM are designed to automatically include relevant interactions for variables included in the model.*** As such, using a GBM to

estimate the PS model, can reduce model misspecification, since ***the analyst is not required to identify relevant interactions or nonlinearities."*** from this citation: PMID: 39947224https://pmc.ncbi.nlm.nih.gov/articles/PMC11825193/

Current propensity score uses **age_at_encounter + sex + race_ethnicity** (remember - have to specify to use this as a factor variable) **+ curr_bmi + copd + asthma + osa + chf + acute_nmd + phtn + location (as a factor variable)**

Note: for all these, I suggested new GBM adjustments that accomplish the following:

1. Smaller GBM & stopping rule → faster fit, avoids over-fitting, lighter tails (which lead to extreme weights that are problematic).
2. bal.tab() documents balance; aim is to adjust spec until standard mean difference (SMD) < 0.1.
3. Weight stabilization (divide by mean) mitigates a few huge weights. I also winsorized, which is a way to avoid very extreme weights (ie you set <1st percentile to the 1st percentile value, and >99th percentile to 99th percentile.
4. Uses robust variance estimation (e.g. allows the variances to change by PaCO2) for IP-weighted GLM; works with splines via rcs(). This is a bit nuanced but I think good to change even though it adds complexity
5. Deterministic seed ensures result replication.

```
subset_data$encounter_type <- factor(subset_data$encounter_type,
                                     levels = c(2, 3),
                                     labels = c("Emergency", "Inpatient"))
```

Added encounter type to weights

```
#   1. fit GBM propensity model, ABG
set.seed(42)

weight_model <- weightit(
  has_abg ~ age_at_encounter + sex + factor(race_ethnicity) + curr_bmi + copd + asthma + osa + chf + acute_nmd + phtn + ckd +

Feature importance: *global* contribution of a feature to the model's predictive performance on the training distribution. Quick global triage—*which variables the model leaned on to fit propensity.* Good for model debugging, feature pruning, and tracking drift across refits (qualitatively).

SHAP: a *local*, signed attribution for that subject: "by how much did feature j push this person's log-odds of receiving the test up or down vs baseline?, then global shap is mean absolute SHAP across subjects—i.e., the **typical magnitude** of a feature's contribution to predictions in your population. Good for auditability and **directional insight**—*who is assigned higher/lower propensity by which features*, spot proxies, and communicate fairness/operational drivers. Aggregate with mean |SHAP| for a **global ranking with direction available** when needed.

TODO: **Can label y-axis in plots: contribution to the log odds of receiving an ABG or VBG for the SHAP values.**

ABG

For the top SHAP-ranked predictors we computed partial- and accumulated-local-effects (ALE) to estimate the marginal change in predicted risk across clinically relevant ranges, robust to covariate correlation. We complemented this with SHAP dependence plots (colored by plausible interactions) and fitted transparent spline-logistic models to identify turn-points ('knees') where marginal log-odds slope changed.
